Windows NT Prefix Table Specification

Author: *Gary D. Kimura*

Revision 1.2, August 2, 1989

1. Introduction.....1

2. Initializing a Prefix Table.....1

3. Adding a New Prefix2

4. Removing a Prefix2

5. Locating a Prefix2

6. Enumerating a Prefix Table.....3

1. Introduction

This specification describes the **Windows NT** routines that implement a prefix table package. The **Windows NT** prefix table package is designed for storing and matching path name prefixes.

The prefix table package exports two opaque types, one is a prefix table used to denote a collection of prefixes, and the other is a prefix table entry used to denote a prefix. A user of this package first initializes a prefix table variable and then either inserts or deletes prefixes, or finds the longest matching prefix in the table.

To utilize this package, the caller needs to define a local structure to contain a prefix table entry. When inserting a new prefix, the caller then supplies a prefix table, prefix string, and a prefix table entry.

To look up a prefix the caller supplies a prefix table and a full path name. If a prefix match is found, the look up procedure returns a pointer to the prefix table entry corresponding to the located prefix. The programmer can then use the `CONTAINING_RECORD` macro to associate the prefix table entry with the local data structures.

Only prefixes that match whole logical parts of a path name are returned. For example, if a table contains the prefix "`\Alpha\Beta`" then a look up on "`\Alpha\`", "`\Alpha\Bet`" and "`\Alpha\BetaGamma`" will be unsuccessful, but a look up on "`\Alpha\Beta`" and "`\Alpha\Beta\Gamma`" will be successful.

The **APIs** that implement the prefix table package are the following:

PfxInitialize - Initialize a prefix table.

PfxInsertPrefix - Add a new prefix to a prefix table.

PfxRemovePrefix - Remove an existing prefix from a prefix table.

PfxFindPrefix - Search a prefix table for the longest matching prefix.

PfxNextPrefix - Enumerate all of the prefixes stored in a prefix table.

2. Initializing a Prefix Table

A prefix table is initialized with the **PfxInitialize** procedure.

VOID

```
PfxInitialize (  
    IN PPREFIX_TABLE PrefixTable  
);
```

Parameters:

PrefixTable - A pointer to the prefix table variable being initialized

A prefix variable cannot be used by the other procedures until it has been initialized.

3. Adding a New Prefix

A user adds a new prefix to a prefix table with the **PfxInsertPrefix** procedure. The prefix is only added if it is not already in the table.

BOOLEAN

```
PfxInsertPrefix (  
    IN PPREFIX_TABLE PrefixTable,  
    IN PSTRING Prefix,  
    IN PPREFIX_TABLE_ENTRY PrefixTableEntry  
);
```

Parameters:

PrefixTable - A pointer to the prefix table being modified

Prefix - The string to add to the prefix table

PrefixTableEntry - A pointer to the prefix table entry to use to denote the prefix

This procedure has a return value of TRUE if the prefix was not already in the table, and FALSE otherwise.

The prefix table keeps a reference to the input *Prefix* string, so once a prefix is added the input string must not be changed by the user.

4. Removing a Prefix

A user removes an existing prefix from a prefix table with the **PfxRemovePrefix** procedure.

VOID

```
PfxRemovePrefix (  
    IN PPREFIX_TABLE PrefixTable,  
    IN PPREFIX_TABLE_ENTRY PrefixTableEntry  
);
```

Parameters:

PrefixTable - A pointer to the prefix table being modified

PrefixTableEntry - A pointer to the prefix table entry to remove from the prefix table

5. Locating a Prefix

A user searches a prefix table for the longest matching prefix with the **PfxFindPrefix** procedure.

PPREFIX_TABLE_ENTRY

```
PfxFindPrefix (  
    IN PPREFIX_TABLE PrefixTable,  
    IN PSTRING FullString,  
    IN BOOLEAN CaseInsensitive  
);
```

Parameters:

PrefixTable - A pointer to the prefix table being queried

FullString - A pointer to the string to use as the key in searching the prefix table

CaseInsensitive - Indicates if the prefix look up should be performed in a manner that ignores the case (*CaseInsensitive* is TRUE) or expects an exact, case sensitive, match (*CaseInsensitive* is FALSE)

This procedure returns a pointer to the prefix table entry corresponding to the longest prefix that matches the input string if one exists and NULL otherwise.

6. Enumerating a Prefix Table

A user can enumerate all of the elements of a prefix table with the **PfxNextPrefix** procedure.

PPREFIX_TABLE_ENTRY

```
PfxNextPrefix (  
    IN PPREFIX_TABLE PrefixTable,  
    IN BOOLEAN Restart  
);
```

Parameters:

PrefixTable - A pointer to the prefix table being enumerated

Restart - Indicates if the enumeration should start over

This procedure returns a pointer to the next prefix stored in the prefix table, or NULL if there are no more entries. The following code fragment illustrates how a programmer uses this procedure to enumerate all of the elements of a prefix table.

```
for (PfxTableEntry = PfxNextPrefix( PrefixTable, TRUE );  
    PfxTableEntry != NULL;  
    PfxTableEntry = PfxNextPrefix( PrefixTable, FALSE )) {  
  
    LocalRecord = CONTAINING_RECORD( PfxTableEntry,  
                                    LOCAL_RECORD,  
                                    PrefixTableEntry);  
  
    ...  
}
```

Revision History:

Original Draft 1.0, August 1, 1989

Revision 1.1, August 2, 1989

1. Added statement concerning how the prefix table keeps a pointer back to the input prefix string.
2. Changed **PfxAddPrefix** to **PfxInsertPrefix**.
3. Dropped *PrefixLength* from **PfxFindPrefix**, and added *CaseInsensitive* parameter.
4. Changed **PfxNextPrefix** prototype and added example of its use.

Revision 1.2, August 3, 1989

1. Changed **PfxFindPrefix** to return a pointer to the table entry if one is found instead of an OUT parameter.
